

zkInterval: Trustless, Confidential, Constant-Size Range Proofs

Quinn Parkinson [✉](#)

Logical Mechanism LLC, USA

Abstract. In this paper, we introduce zkInterval, a novel constant-size zero-knowledge range proof protocol that proves a secret value lies within a public interval without revealing it or requiring a trusted setup. Leveraging Pedersen commitments and advanced zero-knowledge techniques, zkInterval offers a trustless and confidential solution with proofs whose size remains invariant regardless of the interval’s range. This property significantly reduces storage and communication overhead, making zkInterval particularly well-suited for privacy-focused applications and scenarios with variable interval lengths. Our protocol enhances the efficiency and scalability of cryptographic range proofs, offering a robust solution to some critical challenges in modern cryptographic systems.

Keywords: confidentiality · cryptography · information hiding · trustless · zero-knowledge

1 Introduction

Proving that a value lies within a specific interval while preserving its confidentiality poses a significant challenge in cryptographic proofs. Many existing methods generate proofs whose size scales with the interval’s range, which can severely limit their efficiency—especially in applications that demand a constant proof size across variable intervals or must avoid trusted setups, which can introduce vulnerabilities such as collusion-based attacks. In this paper, we introduce zkInterval, a protocol that overcomes these limitations by producing constant-size range proofs independent of the interval’s range without needing a trusted setup. By integrating Weil pairings [?], Pedersen commitments [?], and Schnorr Σ -protocols [?], zkInterval securely demonstrates that a secret value lies within a publicly known interval while keeping the value itself hidden. Our efficient and concise approach makes it particularly well-suited for privacy-focused applications and scenarios with variable interval lengths.

Efficient, privacy-preserving range proofs are essential for applications such as private information verification, secure multi-party computation, and confidential transactions. Although some schemes offer constant-size proofs, they often rely on trusted setups [?] or result in verbose proofs [?]. More recent advancements like Bulletproofs [?] have reduced proof sizes to sublinear scales; however, their proof size still depends on the interval’s range, which can be a limiting factor in applications with variable interval lengths. zkInterval addresses these challenges by delivering constant-size, scalable range proofs that maintain confidentiality without compromising efficiency—attributes especially valuable in blockchain systems and other security-critical applications. This work fills a critical gap in current cryptographic methods and paves the way for further advancements in range-proof technologies.

The remainder of this paper is as follows. Section 2 presents the derivation of the zkInterval protocol, detailing its mathematical foundation and the integration of Weil pairings, Pedersen commitments, and Schnorr Σ -protocols. Section 3 rigorously examines the protocol’s security properties, establishing its zero-knowledge guarantees and demonstrating that it forms a complete proof system. Finally, Section 4 discusses the practical implementation of zkInterval on the Cardano blockchain, highlighting its performance benefits and suitability for privacy-focused and scalable cryptographic applications.

2 Method

The derivation of zkInterval is practical and systematic, structured into distinct sections, each addressing a specific aspect of the proof before being integrated into the final result. We begin with the primary inequality and reformulate it into a suitable polynomial representation. Once in polynomial form, we proceed with the Pedersen commitment scheme to demonstrate that the inequality holds at the commitment level. Subsequently, we will incorporate the commitment scheme into a Weil pairing for any pairing-friendly curve, and then we will finalize the proof with two Schnorr Σ -protocols. The resulting proof is a collection of \mathbb{G}_1 points of the pairing-friendly curve with two integers for the Schnorr Σ -protocols.

We begin the derivation by stating the fundamental inequality that establishes the existence of a value d between a and b ,

$$a \geq d \geq b, \quad (1)$$

where $a \geq b$ and $a, b, d \in \mathbb{Z}^+$. We will introduce two auxiliary variables that quantify the differences between the extremal values a and b and the intermediate value d to reformulate the inequality into a polynomial. The first variable, y , is defined as:

$$a - d = y, \quad (2)$$

and the second variable, w , is defined as:

$$d - b = w. \quad (3)$$

By subtracting equation 3 from equation 2 and reorganizing the terms, we obtain the following equation:

$$a + b + w = y + 2d. \quad (4)$$

Next, we introduce an additional term γ to both sides, resulting in the final fundamental equation:

$$\gamma + a + b + w = y + 2d + \gamma. \quad (5)$$

While adding the γ terms might initially appear redundant, it plays a crucial role when incorporating Pedersen commitments. This inclusion allows us to commit to a value of $\gamma = 0$ while still encapsulating the randomness from the commitment process, thus balancing the randomness by making the blinding factors of the other commitments act like secret keys [?].

To facilitate a more sophisticated exposition of the commitment proof, we shall express the Pedersen commitment scheme in its multiplicative formulation, denoted as $C(v, r) = g^r h^v$, where g and h are designated generators within the \mathbb{G}_1 group of our pairing-friendly elliptic curve. We will use the additive formulation to reconstitute equation 5 in the following manner:

$$C(y, r_y) + 2C(d, r_d) + C(\gamma, \psi) = C(a, r_a) + C(b, r_b) + C(w, r_w) + C(\gamma, \lambda), \quad (6)$$

wherein $\psi = r_a + r_b + r_w$ and $\lambda = r_y + 2r_d$. By imposing $\gamma = 0$, equation 6 reaches a state of equilibrium in its commitment form, thereby enabling each component of equation 5 to be encapsulated within a commitment while preserving the requisite algebraic integrity.

Proof of Pedersen Commitment Scheme. Equation 5 in additive form is:

$$C(y, r_y) + 2C(d, r_d) + C(0, \psi) = C(a, r_a) + C(b, r_b) + C(w, r_w) + C(0, \lambda). \quad (7)$$

The multiplicative form is:

$$g^{r_y} h^y g^{2r_d} h^{2d} g^\psi = g^{r_a} h^a g^{r_b} h^b g^{r_w} h^w g^\lambda. \quad (8)$$

Upon aggregation and simplification, the multiplicative form reduces to:

$$g^{r_y+2r_d+\psi} h^{y+2d} = g^{r_a+r_b+r_w+\lambda} h^{a+b+w}. \quad (9)$$

Recall that $\psi = r_a + r_b + r_w$ and $\lambda = r_y + 2r_d$ which further simplifies the equation to:

$$g^{\lambda+\psi} h^{y+2d} = g^{\psi+\lambda} h^{a+b+w} \quad (10)$$

The definitions of ψ and λ allow the g terms to cancel out.

$$h^{y+2d} = h^{a+b+w} \quad (11)$$

We know from equation 4 that $a + b + w - y - 2d = 0$ thus

$$h^{a+b+w-y-2d} = h^0 = 1 \quad (12)$$

□

The prover must possess comprehensive knowledge of all blinding factors and their aggregate sums and is responsible for constructing the proof with the necessary mathematical rigor. Their key responsibility is to ensure that the commitment form reaches a state of equilibrium and that each component of equation 5 is encapsulated within a commitment.

Now that we have equation 5 and equation 6, we know by proof 2 that the relationship between the variables will hold. However, if we use equation 6, we need additional proofs for each commitment. One way to address this problem is using Weil pairings, which enable global verification, verifying that all the relationships among the commitments hold as expected without having to prove each commitment individually.

The last part of the proof derivation relies on the identity, Galois invariant, and bilinear properties [?] of a Weil pairing. Without loss of generality, we will use the following notation for a Weil pairing:

$$e(Q, P) \rightarrow e(Q, C), \quad (13)$$

where Q is a fixed \mathbb{G}_2 point and C is a Pedersen commitment as a \mathbb{G}_1 point on pairing friendly curve. The Galois invariant property is:

$$e(Q, P)^v = e(Q, vP) \rightarrow e(Q, C(v, r_v)), \quad (14)$$

where r_v is a random blinding factor for the scalar v . The identity property is:

$$e(Q, C(v, r_v))^k = 1, \quad (15)$$

when $k = 0$. The bilinear property is:

$$e(Q, C(v, r_v) + C(u, r_u)) = e(Q, C(v, r_v))e(Q, C(u, r_u)), \quad (16)$$

We start with equation 5 and will work our way into the Weil pairing commitment form similar to equation 6. First, rewrite equation 5 in standard form and substitute the expression for k using the identity property of a Weil pairing. The resulting equation is:

$$e(Q, C(v, r_v))^{y+2d+\gamma-\gamma-a-b-w} = 1. \quad (17)$$

Expand, group terms, and simplify using the invariant and bilinear properties:

$$e(Q, C(y, r_y) + 2C(d, r_d) + C(\gamma, \psi))e(-Q, C(a, r_a) + C(b, r_b) + C(w, r_w) + C(\gamma, \lambda)) = 1. \quad (18)$$

By further simplifying and evaluating γ , we derive the final pairing expression:

$$e(Q, Y + D + \Psi)e(-Q, A + B + W + \Lambda) = 1, \quad (19)$$

Here, the variables are defined as follows:

- $\Psi = C(0, \psi)$ and $\Lambda = C(0, \lambda)$, where $\psi = r_a + r_b + r_w$ and $\lambda = r_y + 2r_d$ represent linear combinations of the blinding factors,
- $Y = C(y, r_y)$ denotes the commitment associated with the scalar y and its corresponding blinding factor r_y ,
- $D = 2C(d, r_d)$ represents a doubled commitment to the scalar d , with r_d as its blinding factor,
- $A = C(a, r_a)$ and $B = C(b, r_b)$ are commitments to the scalars a and b respectively, with r_a and r_b as their respective blinding factors,
- $W = C(w, r_w)$ corresponds to the commitment associated with the scalar w and its blinding factor r_w .

The proof of the Weil pairing is the hexadecimal string:

$$\pi = Y|D|\Psi|A|B|W|\Lambda. \quad (20)$$

To complete the proof, we must show that we have correctly included the interval endpoints a and b because, in the current form, nothing proves that the public endpoints are inside the proof. The commitment for an endpoint in multiplicative form:

$$A = g^{r_a} h^a, \quad (21)$$

Given that a is public and known, we can create a new commitment, C_{r_a} , to prove knowledge of the randomness r_a , thus proving A does indeed use the endpoint a . The commitment C_{r_a} expresses itself as:

$$C_{r_a} = A - C(a, 0) = g^{r_a}. \quad (22)$$

where r_a is the blinding factor. The Schnorr proof for this commitment proceeds as follows:

Proof of Schnorr Proof. Select a random value α , where $\alpha \in \mathbb{Z}^+$. Compute a challenge value

$$c = H(g^\alpha | g^{r_a}), \quad (23)$$

using the Fiat-Shamir heuristic and a public hash function H . Then compute

$$z = \alpha + c \cdot r_a \quad (24)$$

and verify

$$g^z = g^\alpha \cdot C_{r_a}^c. \quad (25)$$

Since

$$g^z = g^{\alpha+c \cdot r_a} = g^\alpha \cdot g^{c \cdot r_a} = g^\alpha \cdot (g^{r_a})^c = g^\alpha \cdot C_{r_a}^c, \quad (26)$$

the proof holds. \square

The prover must provide z in hexadecimal form and g^α for the A and B terms. Together with the pairing equation and the two Schnorr Σ -protocols, this constitutes a complete zero-knowledge proof system for demonstrating that the value d lies between a and b . The final proof is the hexadecimal string:

$$\pi = Y|D|\Psi|A|B|W|\Lambda|g^{r_a}|g^{r_b}|Z_a|Z_b. \quad (27)$$

3 Results

This section may be divided by subheadings. It should provide a concise and precise description of the experimental results, their interpretation as well as the experimental conclusions that can be drawn.

4 Discussion

Authors should discuss the results and how they can be interpreted from the perspective of previous studies and of the working hypotheses. The findings and their implications should be discussed in the broadest context possible. Future research directions may also be highlighted.
